

Learning Community Embedding with Community Detection and Node Embedding on Graphs

By Cavallari et al.

EGOR DMITRIEV, Utrecht University, The Netherlands

1 GOALS

- Guided by the closed loop insight, we propose ComE, a novel Community Embedding framework that **jointly solves community embedding, community detection and node embedding together**.
- Propose: a scalable inference algorithm which complexity of $O(|V| + |E|)$, is often lower than the existing higher-order proximity-aware methods

2 PRELIMINARIES

- Graph $G = (V, E)$

3 CHALLENGES

- Community: Is a group of densely connected nodes
 - Embedding is expected to characterize how its member nodes distribute in the low-dimensional space
 - Define it as a distribution
- Pipeline approach is suboptimal:
 - Because its community detection is independent of its node embedding.
- Most existing node embeddings are not aware of community structure

4 PREVIOUS WORK / CITATIONS

- Don't try to directly detect communities
- Often: don't jointly optimize node embedding and community detection together
- SEA:
 - Construct similarity matrix from spectral GCN embeddings
 - Input it into AE for reconstruction
 - Resulting node embeddings are fed in K-means clustering
 - Shown to perform better than spectral clustering
- M-NMF:
 - Constructs modularity matrix and applies non-negative matrix factorization to learn node embeddings and community detection together
 - Represents each community as a vector!
- **This Work:**
 - Motivated by Gaussian Mixture Models (GMM)
 - Tries to directly detect communities

5 DEFINITIONS

Notation	Description
$G(V, E)$	Graph G , nodes V and edges E
ℓ	Length of each random walk path in sampling
γ	Number of random walks for each node in sampling
ζ	Context size
m	Negative context size
$\phi_i \in \mathbb{R}^d$	Node embedding of node i
$\phi'_i \in \mathbb{R}^d$	Context embedding of node i
$\mathcal{N}(\psi_k, \Sigma_k)$	Community embedding of community k
$\psi_k \in \mathbb{R}^d$	Community embedding k 's mean vector
$\Sigma_k \in \mathbb{R}^{d \times d}$	Community embedding k 's covariance matrix
$\pi_{ik} \in [0, 1]$	Community membership of node i to community k
$P_n(\cdot)$	Negative sampling probability
K	Number of communities on G
α	Trade-off parameter for context embedding
β	Trade-off parameter for community embedding
a	graph's average degree

- **Community detection:** aims to discover groups of nodes on a graph, such that the intra-group connections are denser than the intergroup ones
 - Desired output:
 - * Node embedding $\Phi_i \quad \forall v_i \in V$
 - * Community membership: $\pi_{ik} \quad \forall v_i \in V$
 - * Community embeddings: (Ψ_k, Σ_k)
- **Community embedding:** of community k in d -dimensional space
 - is Multivariate Gaussian distribution: $\mathcal{N}(\Psi_k, \Sigma_k)$

6 OUTLINE / STRUCTURE

- **Community Detection:**
 - Considering v_i and embeddings ϕ_i as generated by multivariate Gaussian distribution from a community $z_i = k$, then for all nodes v we have likelihood:
 - * $\prod_{i=1}^{|V|} \sum_{k=1}^K p(z_i = k) p(v_i | z_i = k; \phi_i, \psi_k, \Sigma_k)$ (eq 1) where
 - $p(z_i = k)$: probability of node v_i belonging to community k (π_{ik})
 - * Rewritten: $p(v_i | z_i = k; \phi_i, \psi_k, \Sigma_k) = \mathcal{N}(\phi_i | \psi_k, \Sigma_k)$ where
 - (Ψ_k, Σ_k) are unknown (optimization target)
 - * Optimizing achieves both community detection and embedding
- **Node embedding:**
 - **First Order Proximity:** Optimizing for direct distance of two nodes
 - * $O_1 = -\sum_{(v_i, v_j) \in E} \log \sigma(\phi_j^T \phi_i)$
 - **Second Order Proximity:** Two nodes sharing many contexts should have similar embedding
 - * Usually through negative sampling
 - $\Delta_{ij} = \log \sigma(\phi_j^T \phi_i) + \sum_{t=1}^m \mathbb{E}_{v_l \sim P_n(v_l)} \left[\log \sigma(-\phi_l^T \phi_i) \right]$
- **Higher-order proximity:** (defined for community detection / embeddings task)
 - two nodes sharing a community are likely to have similar embedding

- $O_3 = -\frac{\beta}{K} \sum_{i=1}^{|V|} \log \sum_{k=1}^K \pi_{ik} \mathcal{N}(\phi_i | \psi_k, \Sigma_k)$
- To close the loop the objective is unified:
 - First, second and higher order proximity should be minimized
 - * $\mathcal{L}(\Phi, \Phi', \Pi, \Psi, \Sigma) = O_1(\Phi) + O_2(\Phi, \Phi') + O_3(\Phi, \Pi, \Psi, \Sigma)$
 - Optimization target:
 - * $(\Phi^*, \Phi'^z, \Pi^*, \Psi^*, \Sigma^*) \leftarrow \arg \min_{\forall k, \text{diag}(\Sigma_k) > 0} \mathcal{L}(\Phi, \Phi', \Pi, \Psi, \Sigma)$
 - * Note that Gaussian component can collapse making diag become zero and O_3 negative infinity
- Inference:
 - Two parts:
 - * Iteratively optimizing (Π, Ψ, Σ) with a constrained minimization given (Φ, Φ')
 - Constraints: $\text{diag}(\Sigma_k) > 0 \quad \forall k \in K$
 - Expectation Maximization algorithm (iteratively update params)
 - * Optimizing (Φ, Φ') with an unconstrained minimization given (Π, Ψ, Σ) .
 - Initialize (Φ, Φ') with deepwalk results
 - * Optimize $\mathcal{L}(\Phi, \Phi', \Pi, \Psi, \Sigma)$ using SGD

7 EVALUATION

- average degree can impact performance due to length and the window size limitation of random walks

8 DISCUSSION

- The part / constraint enforcement for zero checking $\text{diag}(\Sigma_k)$ is not really that convincing

11 NOTES

- What is a modularity matrix?

Algorithm 1 Inference algorithm for ComE

Require: graph $G = (V, E)$, #(community) K , #(paths per node) γ , walk length ℓ , context size ζ , embedding dimension d , negative context size m , parameters (α, β) .

Ensure: node embedding Φ , context embedding Φ' , community assignment Π , community embedding (Ψ, Σ) .

```

1:  $\mathcal{P} \leftarrow \text{SamplePath}(G, \ell)$ ;
2: Initialize  $\Phi$  and  $\Phi'$  by DeepWalk [20] with  $\mathcal{P}$ ;
3: for  $iter = 1 : T_1$  do
4:   for  $subiter = 1 : T_2$  do
5:     Update  $\pi_{ik}$ ,  $\psi_k$  and  $\Sigma_k$  by Eq. 9, Eq. 10 and Eq. 11;
6:     for  $k = 1, \dots, K$  do
7:       if there exists zero in  $\text{diag}(\Sigma_k)$  then
8:         Randomly reset  $\Sigma_k > \mathbf{0}$  and  $\psi_k \in \mathbb{R}^d$ ;
9:     for all edge  $(i, j) \in E$  do
10:      SGD on  $\phi_i$  and  $\phi_j$  by Eq. 14;
11:    for all path  $p \in \mathcal{P}$  do
12:      for all  $v_i$  in path  $p$  do
13:        SGD on  $\phi_i$  by Eq. 15;
14:        SGD on its context  $\phi'_j$ 's within  $\zeta$  hops by Eq. 17;
15:    for all node  $v_i \in V$  do
16:      SGD on  $\phi_i$  by Eq. 16;
```
